(57) **ABSTRACT**

Systems and methods to select peered border elements for a communication session based on Quality-of-Service (QoS) are disclosed. In particular, an example method includes determining a composite QoS parameter of a communication session based on weighting QoS parameters of the session, the QoS parameters including a grade of service parameter of the session and a preferred mode of communication for a voice over Internet protocol (VoIP) device of a called party; querying a telephone number mapping server for a status of each of the peered border elements; assigning the session to be handled by a selected peered border element of the peered border elements based on the composite QoS parameter and the status of each of the peered border elements; and generating a QoS authorization token to reserve network resources associated with the selected peered border element.

SYSTEMS AND METHODS TO SELECT PEERED BORDER ELEMENTS FOR AN IP MULTIMEDIA SESSION BASED ON QUALITY-OF-SERVICE

RELATED APPLICATIONS

This patent arises from a continuation of U.S. patent application Ser. No. 12/037,602, filed on Feb. 26, 2008. The entirety of U.S. patent application Ser. No. 12/037,602 is incorporated herein by reference.

FIELD OF THE DISCLOSURE

This disclosure relates generally to Internet Protocol (IP) Multimedia communications and, more particularly, to systems and methods to select peered border elements for an IP Multimedia session based on Quality-of-Service (QoS).

BACKGROUND

In the field of packet-switched networks, service providers may often have peering relationships with other service providers. Peering relationships provide interconnectivity between the networks of the service providers and allow the customers of peering networks to connect. Peering is typically accomplished at established physical locations or exchange points using peered border elements, through which data may be exchanged between the networks. Two service providers with a peering relationship may maintain multiple exchange points to accommodate large services areas and reduce the distances packet data must travel to reach a destination. For example, two service providers in the United States may maintain exchange points in New York, Chicago, Houston and Los Angeles. Further, each exchange point may feature multiple peered border elements between a given pair of service providers.

Quality-of-Service (QoS), when used in communications, refers to resource reservation control. Implementing QoS may provide different priority levels to different users according to, for example, a customer service contract or an application type. QoS may also guarantee a certain level of performance to a data flow, which can be important when network capacity is limited (i.e., network congestion). Certain applications, such as Voice over Internet Protocol (VoIP), require a certain guarantee of availability and maximum packet delay, which may be provided by a QoS guarantee, to function properly.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic diagram illustrating an example IMS communications system and example call signaling and media flows.

FIG. 2 is a flow diagram illustrating example exchanges and call flows for a VoIP session utilizing Quality-of-Service.

FIG. 3 is a block diagram of an example S-CSCF server as described in connection with FIGS. 1 and/or 2.

FIG. 4 is a block diagram illustrating an example method for selecting a peered border element.

FIG. 5 is a schematic diagram of an example processor platform that may be used and/or programmed to implement the systems described herein.

DETAILED DESCRIPTION

In the interest of brevity and clarity, throughout the following disclosure references will be made to the example Internet protocol (IP) Multimedia subsystem (IMS) based Voice over IP (VoIP) network 110 of FIG. 1. Moreover, the following disclosure will be made using session initiation protocol (SIP) messages and/or SIP-based message exchanges. However, it should be understood that the methods and apparatus described herein to select a peered border element are applicable to other IMS and/or VoIP communication systems and/or networks (e.g., networks based on soft switches), VoIP devices, IMS devices, feature servers, tElephone NUMber mapping (ENUM) servers, border elements, access networks, IP networks, IMS networks and/or IMS communication systems, and/or other types of protocols, messages, and/or message exchanges.

FIG. 1 is a schematic illustration of an example communication system 100 including any number and/or type(s) of VoIP user devices, two of which are designated at reference numerals 105 and 106. Example VoIP user devices 105 and 106 include, but are not limited to, IMS (e.g., VoIP) phones, VoIP residential gateways, VoIP enabled personal computers (PC), VoIP endpoints, wireless VoIP devices (e.g., a wireless-fidelity (WiFi) Internet protocol (IP) phone), VoIP adapters (e.g., an analog telephone adapter (ATA)), VoIP enabled personal digital assistants (PDA), and/or VoIP kiosks. The example VoIP devices 105 and 106 of FIG. 1 may be implemented and/or be found at any number and/or type(s) of locations. Further, the VoIP devices 105 and 106 may be fixed location devices, substantially fixed location devices and/or mobile devices. Moreover, the VoIP devices 105 and 106 may have equipment communicatively and/or electrically coupled to them. For example, a VoIP ATA may be coupled to a telephone, and/or a VoIP residential gateway may be coupled to a PC and/or set-top box. Further still, the VoIP devices 105 and 106 may be associated with the same and/or different service providers. For example as shown in FIG. 1, the VoIP device 105 is associated with a first service provider 110, and the VoIP device 106 is associated with a second service provider 111.

To provide communication services to a first set of subscribers (e.g., associated with a first service provider), the example communication system 100 of FIG. 1 includes an IMS network 110 made available by the service provider A. Likewise, to provide communication services to a second set of subscribers (e.g., associated with a second service provider), the example communication system 100 of FIG. 1 includes any type of IMS and/or VoIP network 111 made available by the service provider B. In some instances, the example calling network 110 implements any or all of the example methods and/or apparatus to select a peered border element described below in connection with the IMS network 111. In general, the example IMS network 110 of FIG. 1 can provide and/or enable IMS communication services (e.g., telephone services, Internet services, data services, messaging services, instant messaging services, electronic mail (email) services, chat services, video services, audio services, gaming services, voicemail, facsimile services, etc.) to the example VoIP device 105, and/or to VoIP devices of other service providers (e.g., the example VoIP device 106).

The example service provider networks 110 and 111 of FIG. 1 are communicatively coupled via any number of pairs of peered border elements. A first pair of peered border elements is designated in FIG. 1 with reference numerals 120 and 121, and a second pair of peered border elements is designated with reference numerals 122 and 123. Mated pairs of peered border elements 120-123 implement, for example, handshaking, media translation(s) and/or protocol message modification(s) to facilitate communication sessions between

subscribers of two service provider networks (e.g., the example networks **110** and **111**).

Typically, the pairs of peered border elements **120**, **121** and **122**, **123** are located so as to provide communicative coupling between the service provider networks **110** and **111** at geographically separated locations. The locations at which peered border elements **120**, **122** are located may differ depending on with which service provider(s) the IMS network **110** has a peering relation. Further, while the service provider **110** of FIG. **1** is illustrated as having a peering relationship with service provider **111**, the service provider **110** may have other peering relationships with other service providers. Moreover, the peering locations for those other service providers may be different from the peering locations for service provider **111**. In some examples, there may be more than one pair of peered bordered elements **120**, **121** and **122**, **123** at a given geographic location. In such examples, the additional peered border elements **120**, **121** and **122**, **123** may be implemented for redundancy purposes and/or to provide additional processing capability(-ies) at that location. In some examples, the peered border elements **120-123** are located at IP peering locations to facilitate deterministic IP Quality-of-Service (QoS). However, not all IP peering locations need support VoIP peering.

To collect real-time and/or dynamic network performance data and/or information, each of the example peered border elements **120** and **122** includes a performance monitor **125**. The example performance monitors **125** of FIG. **1** measure, collect and/or aggregate any number and/or type(s) of data and/or information representative of the historical and/or present performance of the IMS network **110**. Example network performance data and/or information may include, but is not limited to, jitter, round-trip delay, latency, out of order data, data throughput rate, processing load, memory usage, communication path utilization, border element status (e.g., operational, failing and/or failed), etc. The example performance monitors **125** may be configured to collect data within any layer of a protocol stack implemented by the border elements **120** and/or **121**. As described below, the data and/or information measured, collected and/or aggregated by the performance monitors **125** may be used to determine one or more parameters representative of the real-time, dynamic properties of the IMS network **110**, such as routing congestions, overloaded border elements, partially and/or fully failed border elements, etc. In some example, performance monitors **125** may be implemented by other devices of the IMS network **110**, such as routers, switches, hubs, etc. Devices and/or servers of the service provider **111** may also collect real-time and/or dynamic network performance data and/or information. In such instances, the service providers **110** and **111** may exchange collected network performance data and/or information to enable each service provider **110**, **111** to better optimize the performance of their network, but such an exchange is not mandatory for proper implementation of the example methods and apparatus to dynamically select a peered VoIP border element described herein.

To implement the communication services, the example IMS network **110** of FIG. **1** includes an IMS core **130**. To connect a VoIP device (e.g., the VoIP device **105**) to the IMS network **110** and the IMS core **130**, the IMS network provides a proxy call session control function servers (e.g., P-CSCF servers **126**). The P-CSCF server **126** and a second P-CSCF server **127** provide an interface for routing signaling messages to appropriate destinations in the respective IMS networks **110** and **111**. For example, the P-CSCF server **126** may

receive a SIP INVITE message from the VoIP device **105** and forward the message to an appropriate server in the IMS network **110**.

In the illustrated example IMS network **110** of FIG. **1**, each VoIP device (e.g., the example VoIP device **105**) that is registered to the example IMS network **110** is associated with and/or assigned to a serving call session control function (S-CSCF) server (one of which is designated in FIG. **1** with reference numeral **135**). The example S-CSCF1 server **135** of FIG. **1** is responsible for handling incoming and/or outgoing IMS (e.g., VoIP) communication sessions (e.g., telephone calls, data and/or video sessions) associated with its registered VoIP devices (e.g., the VoIP device **105**). Among other functions, the example S-CSCF1 server **135** utilizes QoS and the status of multiple peered border elements to assign a VoIP session (or other voice, data and/or video) to be handled by an appropriate peered border element. To this end, the S-CSCF server calculates and/or receives QoS parameters based on qualities of the VoIP session and uses the QoS parameters to calculate a composite QoS parameter, which is then used to assign an appropriate peered border element from a list of several possible peered border elements. An example operation of the example S-CSCF1 server **135** of FIG. **1** is described below in connection with FIG. **3**.

While one S-CSCF1 server **135** is illustrated in FIG. **1**, the IMS core **130** and/or, more generally, the example IMS network **110** may include any number and/or type(s) of S-CSCF servers, and each such S-CSCF server may support any number and/or type(s) of VoIP devices. The example S-CSCF1 server **135** of FIG. **1** performs session control, maintains session states and/or enables communications with call feature servers (not shown) for its associated and/or registered VoIP devices. For instance, when the VoIP device **105** initiates, for example, an outgoing telephone call to the example VoIP device **106**, a communication session initiation message (e.g., a SIP INVITE message) sent by the VoIP device **105** is routed by the IMS network **110** to the S-CSCF1 server **135** associated with the VoIP device **105**.

To locate and/or identify the VoIP device and/or VoIP endpoint (e.g., the example VoIP device **106**) associated with a called party (e.g., a called telephone number), the example IMS core **130** of FIG. **1** includes any number of ENUM servers, one of which is designated in FIG. **1** with reference numeral **140**. Based upon an ENUM query request message received from a S-CSCF server (e.g., the example S-CSCF1 server **135**), the example ENUM server **140** of FIG. **1** performs a lookup of an ENUM database **145** that stores associations of called party identifiers (e.g., E.164 telephone numbers) to one or more uniform resource identifiers (URIs) (e.g., a SIP URI, an HTTP URI, etc. corresponding to peered border elements and/or called devices). However, an ENUM database may store any number and/or type(s) of associations between any number and/or type(s) of identifiers. The example ENUM server **140** returns the one or more URIs to the S-CSCF1 server **135**.

As described below in connection with FIG. **3**, the example ENUM database **145** may contain more than one database records to associate more than one URI with a particular called party identifier. For example, if a called party (e.g., the VoIP device **106**) is associated with another service provider (e.g., the example network **111**), the ENUM database **145** may contain database records for each of one or more peered border elements **120**, **122** via which the communication session may be established. When two or more database records (e.g., corresponding to two or more peered border elements **120**, **122**) are listed for a called party identifier, each of the database records may have one or more associated values that

represent a relative prioritization of each destination. The priority values (and/or the order in which the database records are listed in the ENUM database **145**) are returned by the ENUM server **140** to the S-CSCF1 server **135** along with the URIs, and allow the S-CSCF1 server **135** to select a particular destination (e.g., a particular peered border element **120**, **122**).

The S-CSCF1 server **135** may also support QoS for VoIP sessions. The QoS requirements for a VoIP session may be different for individual types of sessions. For example, an online gaming application may require a better QoS than a telephone call, where a "better" QoS results in fewer or shorter data packet delays and/or fewer dropped data packets (i.e., higher communication channel quality). Similarly, the relative priorities of peered border elements **120**, **122** in the ENUM database as described above may indicate relative ability to provide QoS to a given VoIP session. Thus, a peered border element **120**, **122** may be appropriately chosen by accounting for peered border element priorities and QoS requirements of VoIP sessions.

To determine the QoS requirements of a VoIP session the S-CSCF1 server **135** in the example defines and considers a number of parameters associated with the session. For example, a Grade of Service (GoS) parameter may be defined for a VoIP device **105**. The GoS, which describes a particular attempted and/or expected performance range, may be associated with a level of service purchased for the VoIP device **105** from the service provider **110** by a customer. The customer purchasing the level of service may own, lease, or borrow the VoIP device **105**. Additionally, each VoIP device **105** and **106** may have its own independent GoS or a shared GoS level based on, for example, a subscriber profile of each device **105** and **106**. The GoS parameter may have values such as, for example, Excellent, Very Good, Good, Fair, and Best Effort (in order from best to worst). Alternatively, the GoS parameter may be described using any number and/or type of values.

To determine GoS for the VoIP device **105**, the S-CSCF1 server **135** may request a subscriber profile, which includes, among other things, the GoS for the VoIP device **105**. The subscriber profile may also be known as a user profile or caller profile. The example subscriber profile for the VoIP device **105** is stored at a Home Subscriber Server (HSS) **165** within the IMS core **130**. Further, although the example S-CSCF1 server **135** determines the composite QoS parameter based at least in part on GoS, the S-CSCF1 server **135** may determine the composite QoS parameter regardless of, in conjunction with, or based purely on GoS and/or the subscriber profile.

Subscriber profiles are based on, for example, customer orders for service. A customer may be any person paying for or receiving for free a network service such as a digital subscriber line (DSL), wireless network access, cable, and/or any other network service. In an example, a customer contacts a service provider (e.g., Service Provider A) and requests service at a particular GoS (e.g., Excellent). The Service Provider A creates a subscriber profile containing, among other things, the GoS level to be received by the customer. The subscriber profile is stored at the HSS **165** and may be used to determine a QoS for a VoIP session associated with the customer. The HSS **165** may also modify an existing subscriber profile if, for example, a customer wishes to upgrade or downgrade the GoS. Further, the customer may interact or contact Service Provider A using any means, such as an Internet-based service ordering system, telephony, electronic mail, or facsimile.

A traffic type parameter may be defined by the S-CSCF1 and used to define QoS for the VoIP session, which may be

defined by the type of application using the session. Example traffic types may include Video, Voice, and Data in order from highest QoS requirement to lowest QoS requirement.

Another parameter that the S-CSCF1 may use to define QoS requirements for a VoIP session specifies a preferred mode of communication for the VoIP device **106** of the called party. The preferred mode of communication parameter may indicate which one of multiple VoIP devices the called party prefers to be reached at and in what order to select each one of the multiple VoIP devices.

A presence mode status parameter may indicate whether the VoIP device **106** associated with the called party is available to be called. For example, if it is known that Service Provider B has a service problem in a portion of the network service the VoIP device **106**, the presence mode status parameter may indicate the VoIP device **106** is not present. The described parameters, or other parameters useful in determining QoS requirements for a VoIP session, may be used to generate a composite QoS parameter. Each parameter may be weighted by relative importance or every parameter may affect the composite QoS parameter equally.

The S-CSCF1 server **135** receives the prioritized list of peered border elements **120**, **122** from the ENUM server **140** and calculates the composite QoS parameter based on the individual QoS parameters. Alternatively, the P-CSCF1 server **126** calculates the composite QoS result from the QoS parameters and sends it to the S-CSCF1 server **135**. From the composite QoS parameter and the prioritized list of peered border elements **120**, **122**, the S-CSCF1 server **135** determines an appropriate peered border element to host the VoIP session. Additionally or alternatively, the S-CSCF1 server **135** may use the prioritized list of peered border elements **120**, **122** and the QoS parameters (e.g., GoS, traffic type, preferred mode of communication and/or presence mode status) to calculate a matrix result, which may score each peered border element **120**, **122** with respect to the VoIP session.

After evaluating the priority of each peered border element **120**, **122** with respect to the composite QoS parameter, the S-CSCF1 server **135** may assign the VoIP session to an appropriate peered border element. In an example situation in which the S-CSCF1 has multiple VoIP sessions queued to be assigned, the S-CSCF1 server **135** may assign the VoIP sessions to peered border elements in the order of highest composite QoS parameter to lowest composite QoS parameter. In such a situation, the network resources may be utilized most effectively to serve the VoIP sessions with the highest QoS requirements. It should be noted that the most appropriate peered border element may not necessarily be the peered border element with the highest QoS capacity. For example, during times of heavy VoIP traffic it may be desirable to assign a VoIP session with a low QoS requirement to a peered border element **120**, **122** that is already heavily loaded, which may free capacity on other peered border elements to handle sessions requiring a higher QoS.

In the absence of priority values (and/or listing order information and/or QoS parameters), the S-CSCF1 server **135** may select a particular destination using any applicable method(s), algorithm(s) and/or logic, such as round-robin selection. A returned URI may also be returned with an indication that the URI is inactive and, thus, not available to be selected and/or used by the S-CSCF1 server **135** for the called party. In some examples, the example ENUM server **140** does not return such inactive URIs to the S-CSCF1 server **135**.

To determine and/or adjust the relative priority of the ENUM database records for called parties, the example IMS core **130** of FIG. **1** includes an operational support system (OSS) server **150**. In the illustrated example of FIG. **1**, the

OSS server **150** represents one or more elements of a network operations center and/or one or more elements of an operational support system. The example OSS server **150** periodically and/or aperiodically collects the network performance data and/or information collected by the example performance monitors **125**. Based on the collected network performance data and/or information, the example OSS server **150** periodically and/or aperiodically computes one or more peered border element metrics that may be used to prioritize the selection of the peered border elements **120**, **122**. For example, the OSS can compute the congestion of communication paths associated with the peered border elements **120**, **122**, the processing load of the peered border elements **120**, **122**, and/or the state(s) of the peered border elements **120,122** (e.g., operational, partially failed, failing and/or failed). Such peered border element metrics may be computed using any past, present and/or future algorithm(s), method(s), apparatus and/or logic, and descriptions of the same are beyond the scope of this disclosure.

Based on the computed peered border element metrics, the example OSS server **150** of FIG. **1** prioritizes the order in which the peered border elements **120**, **122** are to be selected. For example, lightly loaded peered border elements **120**, **122** are preferred over more heavily loaded peered border elements **120**, **122** for VoIP sessions having high QoS requirements, failing and/or failed peered border elements **120**, **122** are to be avoided, peered border elements **120**, **122** having congested communication paths and/or links are less preferable to ones having less congested communication paths and/or links, etc. After prioritizing the peered border elements **120**, **122**, the example OSS server **150** modifies one or more records of the ENUM database **145** to represent the computed relative priorities of the peered border elements **120**, **122**. ENUM database records may be prioritized by modifying priority values of the ENUM database records. Examples of priority values currently used may be the ORDER and PREFERENCE fields, of which the ORDER field has precedence over the PREFERENCE field when considering the relative priority of the ENUM database record. Additionally or alternatively, ENUM database records may be added and/or removed for a particular called party. For example, if a particular peered border element **120**, **122** has failed and, thus, is not available to process a communication session for the called party, its associated ENUM database record may be removed and/or marked as inactive. Likewise, the OSS server **150** may change the status of a particular peered border element **120**, **122** from an inactive state to an active state (e.g., available for routing a communication session) by updating its associated ENUM database record. If a route for a called party is unavailable, the ENUM database may be modified to indicate an alternative route (e.g., use peered border elements **120** and **121** rather than peered border elements **122** and **123**). The OSS server **150** may modify the ENUM database **145** directly by, for example, locking a database record to be changed, modifying the database record, and then unlocking the database record. Additionally or alternatively, the ENUM database **145** may be modified by accessing an application programming interface (API) implemented by and/or provided by the example ENUM server **140**.

The modifications of the ENUM database **145** by the example OSS server **150** of FIG. **1** may be performed without the involvement and/or knowledge of the S-CSCF1 server **135** and/or the ENUM server **140**. In this way, the OSS server **150** can adaptively affect the prioritization of the peered border elements **120**, **122** without there being a need to modify traditional ENUM functions and/or services typically implemented by the S-CSCF1 server **135** and/or the ENUM

server **140**. Moreover, if the method(s) and/or algorithm(s) by which the selection of the peered border elements **120**, **122** are changed, the S-CSCF1 server **135** and/or the ENUM server **140** do not require modification, as the changes may be localized to the OSS server **150**. By prioritizing the peered border elements **120**, **122**, the OSS server **150** reduces the likelihood of routing errors, reduces communication session setup times, adjusts the IMS network **110** in response to failing/failed devices, etc., as compared to traditional peered border elements selection methods.

To resolve a URI to an IP address, the example IMS core **130** of FIG. **1** includes any type of DNS server **155**. For a particular URI (SIP, HTTP and/or otherwise) and using any applicable method(s), logic and/or algorithm(s), the example DNS server **155** performs a DNS lookup to obtain an IP address assigned to and/or associated with the URI.

An application server (AS) **160** may be included in the IMS core **130**. The application server **160** interacts with the SIP INVITE messages on the application layer as defined by the individual implementation. For example, an application server **160** hosting VoIP calls may provide the S-CSCF1 server **135** with values for QoS parameters associated with a VoIP session. Example QoS parameters may include grade of service, traffic type, preferred mode of communication and/or presence mode status, as described above.

While an example IMS network **110** has been illustrated in FIG. **1**, the devices, networks, systems, servers and/or processors illustrated in FIG. **1** may be combined, divided, rearranged, eliminated and/or implemented in any way. For example, it will be readily appreciated by persons of ordinary skill in the art that the example peered border elements **120**, **122**, the example performance monitors **125**, the example IMS core **130**, the example S-CSCF1 server **135**, the example ENUM server **140**, the example OSS server **150**, the example DNS server **155** and the example application server **160** illustrated in FIG. **1** are logical entities. They may, therefore, be implemented separately and/or in any combination using, for example, machine accessible instructions executed by one or more computing devices and/or computing platforms (e.g., the example processing platform **500** of FIG. **5**). Further, the example peered border elements **120**, **122**, the example performance monitors **125**, the example IMS core **130**, the example S-CSCF1 server **135**, the example ENUM server **140**, the example OSS server **150**, the example DNS server **155**, the example application server **160** and/or, more generally, the example IMS network **110** may be implemented by hardware, software, firmware and/or any combination of hardware, software and/or firmware. Further still, the example IMS network **110** may include additional devices, servers, systems, networks, gateways, portals, and/or processors in addition to, or instead of, those illustrated in FIG. **1** and/or may include more than one of any or all of the illustrated devices, servers, networks, systems, gateways, portals, and/or processors. For example, the IMS core **130** may include and/or utilize one or more of a P-CSCF server, an S-CSCF server, an interrogating CSCF server, a feature server, an application server, an HSS, a media gateway, a breakout gateway control function (BGCF) server, a media gateway control function (MGCF) server, a softswitch, an IP router, an IP switch, etc.

Although the systems and methods described herein are discussed with reference to example VoIP sessions, it is contemplated that the described systems and methods may be used for any voice, video and/or data communications where QoS may be applied. Additionally, either or both of the VoIP devices **105** and **106** may be replaced by or may complement other devices, such as mobile devices or video conferencing

devices. The systems and methods described here may also be applied to mobile telecommunications and data services using QoS.

FIG. 2 illustrates example protocol message exchanges and flowcharts representative of processes that may be carried out by, for example, machine executable instructions on a processor to implement the example IMS networks 110 and 111 of FIG. 1. The VoIP device 105 associated with a calling party initiates a session by sending a SIP INVITE message 225 to the S-CSCF 135 of FIG. 1 via a Proxy-CSCF1 (P-CSCF1) server 126 and/or an access border element (not shown). The P-CSCF1 server 126 routes SIP INVITE message 230 to the S-CSCF1 server 135 that has previously registered or been registered with the VoIP device 105.

The example S-CSCF server 135 receives the SIP INVITE message and forwards the SIP INVITE message 235 to an application server (AS) 160. The application server 160 may help determine QoS parameters associated with the VoIP session by, for example, providing grade-of-service information for the calling VoIP device 105. The application server 160 may return one or more QoS parameter values to the S-CSCF1 server 135 in response 240 to the SIP INVITE message 235.

After the S-CSCF1 server 135 receives QoS parameters from the AS 160, the S-CSCF1 server 135 enters block 245 to select a peered border element 120, 122 to handle the VoIP session. To select a peered border element 120, 122, the S-CSCF1 server 135 queries the ENUM server 140 to resolve the called party E.164 destination (e.g., dialed phone number) from the INVITE message into a destination (e.g., SIP URI) and to return a list of peered border elements. Upon receiving the request, the ENUM server 140 resolves the called party E.164 destination to a SIP URI address. Resolving the E.164 destination to a SIP URI address may be accomplished by consulting an ENUM database, which holds records mapping, for example, E.164 destinations or telephone numbers to SIP URI addresses. The ENUM database may also include records of peered border elements, which may be updated periodically to reflect real-time network conditions as described above. Each peered border element record may be associated with one or more priority fields, indicating the relative capability of each peered border element to support QoS loads. The peered border element records may be organized into a list ordered by priority.

The ENUM server returns the SIP URI address and the list of prioritized peered border elements to the S-CSCF1 server 135. The S-CSCF1 server 135, now having knowledge of the VoIP device 105 associated with the calling party and the VoIP device 106 associated with the called party, determines any remaining QoS parameters associated with the session. The QoS parameters may include Grade of Service, traffic type, preferred mode of communication, presence mode status, and/or any other parameter that may describe the QoS requirements of the VoIP session and have not been received from an external source (e.g., the P-CSCF1 server 126, the application server 160). After identifying the values associated with the QoS parameters, the S-CSCF1 server 135 calculates a composite QoS parameter. Using the composite QoS parameter and the list of prioritized peered border elements, the S-CSCF1 server 135 determines an appropriate peered border element 120, 122 to handle the VoIP session.

After a peered border element (e.g., peered border element 122) is selected (block 245), the S-CSCF1 server 135 forwards the SIP INVITE message 250 to an appropriate S-CSCF2 server 220 associated with Service Provider B. The S-CSCF2 server 220 may communicate 255 with the application server 160 or a different application server to register a

QoS treatment for the session. After receiving a response 260 from the application server 160, the S-CSCF2 server 220 forwards the SIP INVITE message 265 to the P-CSCF1 server 126. The P-CSCF1 server 126 then sends an INVITE message 270 including the URIs for the device 106 to the selected peered border element 120, 122, which pre-alerts the called device 106 via the corresponding peered border element 121, 123. Exchanges (e.g., 225, 230, 235) shown in FIG. 2 may be performed and/or responded to by standard messages such as, for example, SIP INVITE, 100 Trying, 183 Session Progress, and/or 200 OK.

When the VoIP device 106 has been pre-alerted to the session, the VoIP devices 105 and 106 negotiate and establish the communication session 280. For example, the IMS systems 110 and 111 begin to reserve network resources to provide QoS for the VoIP session. QoS resource reservation may occur according to published standards. For example, the P-CSCF1 server 126 and the P-CSCF2 server 127 may generate a Packet Data Protocol (PDP) or other appropriate context and issue QoS authorization tokens to the respective VoIP devices 105 and 106 for use with the selected peered border element 120, 122. PDP is a network protocol used by packet switching networks to communicate with general packet radio services (GPRS) networks. The PDP context includes the QoS profile. The authorization token may be sent as a part of the packet data associated with the VoIP session, which alerts the peered border elements supporting the call to the priority of the packet data.

FIG. 3 is a block diagram of an example S-CSCF server 135 as described in connection with FIGS. 1 and/or 2. The example S-CSCF server 135 includes a receiver 305, a Composite QoS Parameter Generator 310, a Peered Border Element Selector 315, and a Peered Border Element Notifier 320. The receiver 305 is communicatively coupled to the example ENUM server 140 and example OSS server 150 described in connection with FIGS. 1 and/or 2. When the S-CSCF server 135 selects a peered border element 120, 122 to host a VoIP session, the receiver 305 receives a prioritized list of peered border elements and corresponding priority values from the ENUM server 140 and one or more QoS parameters from, for example, the P-CSCF1 server 126. The prioritized list is passed to the Peered Border Element Selector 315 and any received QoS parameters are passed to the Composite QoS Parameter Generator 310.

The Composite QoS Parameter Generator 310 receives QoS parameters from the receiver 305, a SIP INVITE message (e.g., the message described in connection with FIG. 2) and/or other sources and generates a composite QoS parameter associated with the VoIP session. The composite QoS parameter is then passed to the Peered Border Element Selector 315. The Peered Border Element Selector 315 receives the composite QoS parameter and the prioritized list and selects a peered border element 120, 122 from the prioritized list based on the priority values and the composite QoS parameter. For example, the Peered Border Element Selector 315 selects one of the peered border elements 120 or 122 that has the highest priority value for a VoIP session with the highest composite QoS parameter.

When a peered border element 120, 122 is selected for the VoIP session, the Peered Border Element Notifier 320 notifies the selected peered border element 120, 122 via the appropriate channels. The Peered Border Element Notifier 320 registers the QoS treatment for the VoIP session with the selected peered border element 120, 122 and the P-CSCF servers 126 and 127 generate a PDP context and QoS authorization tokens.

The example S-CSCF server **135** as shown in FIG. **3** includes but does not show functionality currently attributed to S-CSCF servers by those of ordinary skill in the art to emphasize using the composite QoS parameter and the prioritized list of peered border elements to assign a voice, data and/or video session to a peered border element.

FIG. **4** illustrates example machine accessible instructions that may be executed to implement any or all of the example S-CSCF servers **135** and/or **220** of FIGS. **1-3**. The example protocol exchanges and/or the example machine accessible instructions of FIGS. **2** and/or **4** may be carried out by a processor, a controller and/or any other suitable processing device. For example, the example protocol exchanges and/or the machine accessible instructions of FIGS. **2** and/or **4** may be embodied in coded instructions stored on a tangible medium such as a flash memory, a ROM and/or RAM associated with a processor (e.g., the example processor **505** discussed below in connection with FIG. **5**). Alternatively, some or all of the example protocol exchanges and/or the machine accessible instructions of FIGS. **2** and/or **4** may be implemented using any combination(s) of application specific integrated circuit(s) (ASIC(s)), programmable logic device(s) (PLD(s)), field programmable logic device(s) (FPLD(s)), discrete logic, hardware, firmware, etc. Also, some or all of the example protocol exchanges and/or the machine accessible instructions of FIGS. **2** and/or **4** may be implemented manually or as any combination of any of the foregoing techniques, for example, any combination of firmware, software, discrete logic and/or hardware. Further, persons of ordinary skill in the art will readily appreciate that many other methods of implementing the example operations of FIGS. **2** and/or **4** may be employed. For example, the order of execution of the blocks may be changed, and/or one or more of the blocks described may be changed, eliminated, sub-divided, or combined. Additionally, persons of ordinary skill in the art will appreciate that any or all of the example protocol exchanges and/or the machine accessible instructions of FIGS. **2** and/or **4** may be carried out sequentially and/or carried out in parallel by, for example, separate processing threads, processors, devices, discrete logic, circuits, etc.

FIG. **4** illustrates an example process that may be executed to implement the example S-CSCF server **135** of FIGS. **1** and/or **2**. The method **400** begins by receiving a SIP INVITE message (block **410**). The SIP INVITE message may include information describing a desired device to include in the session (i.e., a called party) such as, for example, a URL address or a SIP URI for use in querying a DNS server or an ENUM server. The S-CSCF server may then query an ENUM server (e.g., the example ENUM server **140** illustrated in FIGS. **1** and/or **2**) and/or a DNS server, based on the information received in the SIP INVITE message (block **420**). In an example, the S-CSCF server queries the ENUM server based on an E.164 telephone number. The example ENUM server returns a SIP URI address and a prioritized list of peered border elements as described above to the S-CSCF server (block **430**).

After receiving the SIP URI address and the prioritized list of peered border elements, the S-CSCF server may calculate a composite QoS parameter from multiple QoS parameters associated with the VoIP session (block **440**). For example, the S-CSCF server may calculate a composite QoS parameter from a GoS parameter, a traffic type parameter, a preferred mode of communication parameter, and a presence mode status parameter as described above in connection with FIG. **1**. Alternatively, the S-CSCF server may receive the composite QoS parameter calculated from the QoS parameters by another server such as, for example, the P-CSCF server rout-

ing the message from the VoIP device. The composite QoS parameter may then be used to compare the priority values of each peered border element and select a peered border element based on the comparison (block **450**). An example selection may include selecting a peered border element with a high priority value to handle a VoIP session with a high composite QoS parameter. Additionally or alternatively, the S-CSCF server may pass the VoIP session to a queue to be assigned in a particular order. When the VoIP session is assigned to a peered border element, the S-CSCF may relinquish control to another server to begin QoS resource reservation (block **460**).

As an alternative to assigning an IP multimedia session to one of the available peered border elements, the peered border elements **120, 122** may be partitioned into p groups, where p is the number of grades of service. The peered border elements **120, 122** may be partitioned into groups equally or unequally, and/or they may be assigned to groups based on relative serving capability. For the example grades of service described above, a group of 100 peered border elements **120, 122** are partitioned into 5 groups. Each group, Excellent, Very Good, Good, Fair, and Best Effort has 20 peered border elements **120, 122** to serve IP multimedia sessions. The 20 peered border elements **120, 122** in the Excellent group have the greatest serving capacity for IP multimedia sessions, the 20 peered border elements **120, 122** in the Very Good group have the next best serving capacity, etc. The peered border elements **120, 122** may alternatively be assigned to a group dynamically, based on the serving capacity relative to the other available peered border elements **120, 122**. Although only two peered border elements **120, 122** are shown for clarity, more such peered border elements may exist and can be accommodated, as described herein.

The S-CSCF1 server **135** assigns an IP multimedia session to a peered border element **120, 122** in a group based on the GoS of the calling party, which is retrieved as part of the subscriber profile from the HSS **165**. The assignment to the peered border element **120, 122** may occur based on any algorithm to select a peered border element **120, 122** from the group corresponding to the GoS of the calling party. Alternatively, the S-CSCF1 server **135** may receive a list of peered border elements as described above, where the list also includes the group information for each peered border element **120,122**. In this case, the S-CSCF1 server **135** assigns the IP multimedia session to a peered border element **120, 122** from the group corresponding to the GoS of the calling party **105**.

FIG. **5** is a schematic diagram of an example processor platform **500** that may be used and/or programmed to implement all or a portion of any or all of the example VoIP devices **105** and/or **106**, the example peered border elements **120, 122**, the example performance monitors **125**, the example P-CSCF servers **126** and **124**, the example S-CSCF server **135**, the example ENUM server **140**, the example OSS server **150**, the example DNS server **155**, and/or the application server **160** of FIGS. **1-3**. For example, the processor platform **500** can be implemented by one or more general purpose processors, processor cores, microcontrollers, etc.

The processor platform **500** of the example of FIG. **5** includes at least one general purpose programmable processor **505**. The processor **505** executes coded instructions **510** and/or **512** present in main memory of the processor **505** (e.g., within a random-access memory (RAM) **515** and/or a read-only memory (ROM) **520**). The processor **505** may be any type of processing unit, such as a processor core, a processor and/or a microcontroller. The processor **505** may execute, among other things, the example protocol message exchanges

13

and/or the example protocol exchanges and/or the example machine accessible instructions of FIGS. 2 and/or 4 to implement the example methods and apparatus described herein.

The processor 505 is in communication with the main memory (including a ROM 520 and/or the RAM 515) via a bus 525. The RAM 515 may be implemented by DRAM, SDRAM, and/or any other type of RAM device, and ROM may be implemented by flash memory and/or any other desired type of memory device. Access to the memory 515 and the memory 520 may be controlled by a memory controller (not shown). One or both of the example memories 515 and 520 may be used to implement the example ENUM database 155 of FIG. 1.

The processor platform 500 also includes an interface circuit 530. The interface circuit 530 may be implemented by any type of interface standard, such as an external memory interface, serial port, general purpose input/output, etc. One or more input devices 535 and one or more output devices 550 are connected to the interface circuit 530.

Of course, persons of ordinary skill in the art will recognize that the order, size, and proportions of the memory illustrated in the example systems may vary. Additionally, although this patent discloses example systems including, among other components, software or firmware executed on hardware, it will be noted that such systems are merely illustrative and should not be considered as limiting. For example, it is contemplated that any or all of these hardware and software components could be embodied exclusively in hardware, exclusively in software, exclusively in firmware or in some combination of hardware, firmware and/or software. Accordingly, persons of ordinary skill in the art will readily appreciate that the above described examples are not the only way to implement such systems.

At least some of the above described example methods and/or apparatus are implemented by one or more software and/or firmware programs running on a computer processor. However, dedicated hardware implementations including, but not limited to, an ASIC, programmable logic arrays and other hardware devices can likewise be constructed to implement some or all of the example methods and/or apparatus described herein, either in whole or in part. Furthermore, alternative software implementations including, but not limited to, distributed processing or component/object distributed processing, parallel processing, or virtual machine processing can also be constructed to implement the example methods and/or apparatus described herein.

It should also be noted that the example software and/or firmware implementations described herein are optionally stored on a tangible storage medium, such as: a magnetic medium (e.g., a disk or tape); a magneto-optical or optical medium such as a disk; or a solid state medium such as a memory card or other package that houses one or more read-only (non-volatile) memories, random access memories, or other re-writable (volatile) memories; or a signal containing computer instructions. A digital file attachment to e-mail or other self-contained information archive or set of archives is considered a distribution medium equivalent to a tangible storage medium. Accordingly, the example software and/or firmware described herein can be stored on a tangible storage medium or distribution medium such as those described above or equivalents and successor media.

To the extent the above specification describes example components and functions with reference to particular devices, standards and/or protocols, it is understood that the teachings of the invention are not limited to such devices, standards and/or protocols. Such systems are periodically superseded by faster or more efficient systems having the

14

same general purpose. Accordingly, replacement devices, standards and/or protocols having the same general functions are equivalents which are intended to be included within the scope of the accompanying claims.

Although certain example methods, apparatus and articles of manufacture have been described herein, the scope of coverage of this patent is not limited thereto. On the contrary, this patent covers all methods, apparatus and articles of manufacture fairly falling within the scope of the appended claims either literally or under the doctrine of equivalents.

What is claimed is:

1. A method for assigning a plurality of peered border elements, comprising:

determining a composite Quality-of-Service parameter of a communication session based on weighting Quality-of-Service parameters of the communication session, the Quality-of-Service parameters including a grade of service parameter of the communication session and a preferred mode of communication for a voice over Internet protocol device of a called party, the grade of service parameter including an attempted performance range and an expected performance range of the communication session, the grade of service parameter based on a level of service purchased for a device that is an endpoint of the communication session, and the preferred mode of communication indicating which one of multiple voice over Internet protocol devices the called party prefers to be reached at and in what order to select each one of the multiple voice over Internet protocol devices;

querying a telephone number mapping server for a status of each of the peered border elements;

assigning the communication session to be handled by a selected peered border element of the peered border elements based on the composite Quality-of-Service parameter and the status of each of the peered border elements; and

generating a Quality-of-Service authorization token to reserve network resources associated with the selected peered border element.

2. A method as defined in claim 1, wherein the communication session comprises a voice over Internet protocol session.

3. A method as defined in claim 1, wherein the status comprises real-time network conditions.

4. A method as defined in claim 1, further comprising assigning a second communication session to be handled by a second selected peered border element of the peered border elements based on a second composite Quality-of-Service parameter prior to assigning the first communication session, based on relative values of the first composite Quality-of-Service parameter and the second composite Quality-of-Service parameter.

5. A method as defined in claim 1, further comprising at least one of creating, modifying, and using a subscriber profile based on the grade of service parameter, the composite Quality-of-Service parameter being based on the subscriber profile.

6. A method as defined in claim 1, further comprising partitioning the plurality of peered border elements into sets based on the grade of service parameter, the communication session to be handled by the selected peered border element, the selected peered border element selected from one of the sets based on the composite Quality-of-Service parameter and the respective statuses of the sets.

7. A system to assign a communication session to a selected peered border element associated with a service provider, the system comprising:

15

a telephone number mapping database to store a list of peered border elements;

an operations support system to prioritize the peered border elements in the list based on a respective status of the peered border elements;

a composite Quality-of-Service parameter generator to determine a composite Quality-of-Service parameter of the communication session by weighting Quality-of-Service parameters of the communication session including a grade of service parameter of the communication session and a preferred mode of communication for a voice over Internet protocol device of a called party, the grade of service parameter including an attempted performance range and an expected performance range of the communication session, the grade of service parameter being based on a level of service purchased for a device that is an endpoint of the communication session, and the preferred mode of communication indicating which of multiple voice over Internet protocol devices the called party prefers to be reached at and in what order to select each of the multiple voice over Internet protocol devices;

a call server to select the selected peered border element to handle the communication session based on the prioritized list and the composite Quality-of-Service parameter of the communication session; and

a proxy server to generate a Quality-of-Service authorization token to reserve network resources associated with the selected peered border element.

8. A system as defined in claim 7, wherein the communication session comprises a voice-over-Internet protocol session.

9. A system as defined in claim 7, further comprising a home subscriber server to at least one of create, modify, and use a subscriber profile based on the grade of service parameter, the call server to select peered border element based on the subscriber profile.

10. A system as defined in claim 7, wherein the call server selects the selected peered border element from the peered border elements based on the grade of service parameter.

11. A tangible computer readable storage device comprising computer readable instructions which, when executed, cause a processor to perform operations comprising:

determining a composite Quality-of-Service parameter of a communication session based on weighting a plurality of Quality-of-Service parameters of the communication session, the Quality-of-Service parameters including a grade of service parameter of the communication ses-

16

sion and a preferred mode of communication for a voice over Internet protocol device of a called party, the grade of service parameter including an attempted performance range and an expected performance range of the communication session, the grade of service parameter based on a level of service purchased for a device that is an endpoint of the communication session, and the preferred mode of communication indicating which one of multiple voice over Internet protocol devices the called party prefers to be reached at and in what order to select each one of the multiple voice over Internet protocol devices;

querying a telephone number mapping server for a status of each of a plurality of peered border elements;

assigning the communication session to be handled by a selected peered border element of the peered border elements based on the composite Quality-of-Service parameter and the status of each of the peered border elements; and

generating a Quality-of-Service authorization token to reserve network resources associated with the selected peered border element.

12. A storage device as defined in claim 11, wherein the communication session comprises a voice-over-Internet protocol session.

13. A storage device as defined in claim 11, wherein the status comprises real-time network conditions.

14. A storage device as defined in claim 11, further comprising assigning a second communication session to be handled by a second selected peered border element of the peered border elements based on a second composite Quality-of-Service parameter prior to assigning the first communication session, based on relative values of the first composite Quality-of-Service parameter and the second composite Quality-of-Service parameter.

15. A storage device as defined in claim 11, further comprising at least one of creating, modifying, and using a subscriber profile based on the grade of service parameter, the composite Quality-of-Service parameter being based on the subscriber profile.

16. A storage device as defined in claim 11, further comprising partitioning the plurality of peered border elements into sets based on the grade of service parameter, the communication session to be handled by the selected peered border element the selected peered border element selected from one of the sets based on the composite Quality-of-Service parameter and the respective statuses of the sets.
